

ARIMA AND PHILLIPS CURVES IN FINDING THE CZECH POTENTIAL RATE OF UNEMPLOYMENT

Ondřej Šimpach, Helena Chytilová

Key words: inflation rate, unemployment rate, ARIMA, Phillips curve, forecast

Abstract

The aim of this study is to assess the potential relationship between inflation and unemployment rate in the Czech Republic in light of classical Phillips curve approach. In some countries the assumptions of use of Phillips curve proved to perform very well, however this is not always the case. In some periods of time it is possible to apply Phillips curve for forecasting the future inflation and future unemployment, because of existing causal relationship. But this causal relationship might not be necessarily valid for all years and the Czech Republic is not the exemption. As a result the assumptions of Phillips curve for the Czech Republic might be limited in their effect. Using the latest available data, above-mentioned relationship will be analysed. In addition, forecasts of inflation and unemployment rate will be calculated using the Phillips curve and subsequently compared with the predictions resulting from the ARIMA model approach.

Introduction

Followed by Phelps (1967) and Friedman (1968) interpretation of the Phillips curve, which introduced the concept of the natural rate of unemployment, the simple relationship between inflation and unemployment rate introduced originally by Phillips (1958), apparently weakened. In light of this development, the empirical Phillips curve is widely discussed phenomenon, where under certain conditions it is possible to find a potential relationship between inflation and unemployment rate. This inflation or unemployment rate is possible to expect and anticipate. Recent studies have proved an observable short-term Phillips curve by estimating a time-varying natural rate of unemployment, followed by examination of deviations of unemployment from its natural rate with regards to inflation. See for instance, King and Watson (1994), in King and Morley (2007), and in Lee and Nelson (2007), where evidence of measurable Phillips curve is provided. In many studies the analysis has been conducted primarily for the United States, United Kingdom, Japan and other major world economies. The reason behind it is that bigger world economies have been existing for a long time and that there is a sufficient amount of data (see e.g. Dittmar and Gavin, (2000)). Since Czech Republic is a young country, there is not enough data, but by using quarterly data published by the Czech Statistical Office (CZSO), it is possible to capture at certain time periods these short or medium-long terms at the moments.

Expecting future inflation or unemployment rate can be either intuitively from the graph, or using linear or polynomial regression. Because of short cycles in the Czech Republic, which took place during its short development, there is unfortunately not enough data for polynomial regression and linear approach can be applied only. For the purpose of this study data with quarterly frequencies will be used, published by CZSO. To express the inflation rate, consumer price indices (CPI) will be used, related to the average of basic year 2005. To express the unemployment rate there will be used the common unemployment rate in %. Particular observations start on 1st quarter 2000 and end on 2nd quarter 2012. The 1st and 2nd quarter 2012 are only preliminary estimates, but will be also included in analysis.

The work is divided into two parts. The first part of study aims to present the situation in the Czech Republic from 2000 to present. In this section, economic development of the Czech Republic will be divided into several cycles, in which apparent potential relationship between inflation and unemployment rate might be seen. The first cycle will be apparent for the situation from 1st quarter 2000 to 4th quarter 2003. The second cycle took place from 1st quarter 2004 to 4th quarter 2008. It was a period of acceleration of the economy until the outbreak of the economic crisis. Period of 2009 is left separately as the year of economic recovery and return to potential rate of unemployment (see e.g. Kiley, (1998) or Kydland and Prescott (1977)). From 1st quarter 2010 to the present, comes the latest separate cycle, which could be called a period of accelerating inflation. For these three mentioned cycles there will be constructed the regression models and will be expressed the relationship between inflation and unemployment rate.

In the second part of the analysis suitable ARIMA model for time series of inflation and unemployment rate will be identified, using methodological approach of Box and Jenkins, (1970). Using the estimated models, projections will be constructed for inflation and unemployment rate up to 4th quarter of 2015. Trough evaluation of results illustrated also in the chart of Phillips curve, we may presume that the assumptions of future accelerating inflation are strong. Based on results obtained, the Czech Republic is expected to stay at long-range potential rate of unemployment, but there is a dangerous of continual and uncontrolled accretion of the price level over time.

1. Development of inflation and unemployment rate

The development of Phillips curve in the Czech Republic from 1st quarter 2000 to 2nd quarter 2012 is shown in Figure 1. The rate of inflation, expressed by the CPI was in contradiction with an average of 2005 at 88.6% level. The unemployment rate was 9.5 % at that time.

Fig. 1 - The development of Phillips curve for the Czech Republic from 1st quarter 2000 to 2nd quarter 2012, where INFLAT is Consumer Price Index (+100 %, the average of 2005 is 100 %) and UNEMP is unemployment rate in %.

Source: CZSO, own construction.

As time went on, the unemployment declined with slight fluctuations, the price level gradually grew over time until the end of 2003. This partial development of the Phillips curve is shown in Figure 2. We can see that at the end of 2003 the inflation rate was approximately at the 95.5 % of level of the average of 2005 and the unemployment rate was approximately 8.1 %. This is the first continuous cycle of Phillips curve, and as a result linear regression model will be applied. Estimates of unknown parameters are shown in Table 1.

Fig. 2 - The partial development of Phillips curve for the Czech Republic from 1st quarter 2000 to 4th quarter 2003, where INFLAT is Consumer Price Index (+100 %, the average of 2005 is 100 %) and UNEMP is unemployment rate in %.

Table 1 - Linear regression model, situation from 1st quarter 2000 to 4th quarter 2003

Parameter	Estimate	St. Error	T Statistic	P-Value
Intercept	20.6995	4.96376	4.17013	0.0009
Slope	-3.40572	0.619126	-5.50086	0.0001

Source: own construction

The diagnostic tests of the model indicate absence of autocorrelation and heteroscedasticity at the 5% significance level. The correlation between inflation and unemployment rate is -0.83, i.e. a strong indirect dependency. Adjusted index of determination $adj.R^2$ is 66.1 %, therefore this simple model explains almost two thirds of the variance. The final regression is shown in Figure 3.

Fig. 3 - Regression model for the situation in Czech Republic from 1st quarter 2000 to 4th quarter 2003, where INFLAT is Consumer Price Index (+100 %, the average of 2005 is 100 %) and UNEMP is unemployment rate in %.

Source: own construction.

Since 2004, there was a process of acceleration of the Czech economy. The product has grown, the economy prospered and the unemployment rate gradually declined to a very favourable, but long-term unsustainable level. From 8.7 % in 2004 the unemployment rate declined to 4.4 % at the end of 2008. The inflation rate, expressed by the CPI grew slowly from 97.6 % to 112.2 % of level of the average in 2005. Development of this accelerating period is shown in Figure 4. It is a period of considered second cycle, and therefore another linear regression model will be estimated. Estimates of unknown parameters are shown in Table 2.

Table 2 - Linear regression model, situation from 1st quarter 2004 to 4th quarter 2008

Parameter	Estimate	St. Error	T Statistic	P-Value
Intercept	23.6325	1.55165	15.2305	0.0000
Slope	-3.02151	0.22793	-13.2563	0.0000

Fig. 4 - The partial development of Phillips curve for the Czech Republic from 1st quarter 2004 to 4th quarter 2008, where INFLAT is Consumer Price Index (+100 %, the average of 2005 is 100 %) and UNEMP is unemployment rate in %.

Source: CZSO, own construction.

The diagnostic tests of the model indicate the absence of autocorrelation and heteroscedasticity at the 5% significance level. The correlation between inflation and unemployment rate is -0.95, i.e. a very strong indirect dependency. Adjusted index of determination $adj.R^2$ is 90.2 %, therefore this simple model explains the most of the variance. The final regression is shown in Figure 5.

At the end of 2008 came the economic crisis. Overheated economy of the Czech Republic slowed and the domestic product began to decline. For this reason, the unemployment began to rise again from the initial low level to 5.8 % in 1st quarter, to 6.3 % in 2nd quarter, to 7.3 % in 3rd quarter and to 7.2 % in the 4th quarter of 2009. During this period the price level slightly decreased. It decreased from 113.6 % in 1st quarter of 2009 successively to 112.7 % in 4th quarter of 2009 in confrontation with an average of 2005. This situation is shown separately in Figure 6.

Fig. 5 - Regression model for the situation in Czech Republic from 1st quarter 2004 to 4th quarter 2008, where INFLAT is Consumer Price Index (+100 %, the average of 2005 is 100 %) and UNEMP is unemployment rate in %.

Fig. 6 - The situation of the Czech Republic during economic slowdown from 1st quarter 2009 to 4th quarter 2009 (return to potential unemployment rate), where INFLAT is Consumer Price Index (+100 %, the average of 2005 is 100 %) and UNEMP is unemployment rate in %.

Source: CZSO, own construction.

The last cycle, the recovery from the crisis is shown in Figure 7. It is a development from 1st quarter of 2010 to the present. Last published values from CZSO are 1st and 2nd quarter of 2012 and these are preliminary estimates. The situation, which is shown in the Figure 7, has the character of the accelerating inflation (see Dittmar and Gavin, 2000). Given not enough observations (only 10) and with great variance, the slope in the final regression in Table 3 is statistically insignificant. There is shown a square in Figure 7, in which the estimates of inflation and unemployment rate for 3rd and 4th quarter of the 2012 might be intuitively found.

Fig. 7 - The situation of the Czech Republic from 1st quarter 2010 to 2nd quarter 2012 and the potential coordinates of forecast for 3rd and 4th quarter 2012, where INFLAT is Consumer Price Index (+100 %, the average of 2005 is 100 %) and UNEMP is unemployment rate in %.

Table 3 - Linear regression model, situation from 1st quarter 2010 to 2nd quarter 2012 and the statistical insignificance of slope.

Parameter	Estimate	St. Error	T Statistic	P-Value
Intercept	33.3295	11.2946	2.95091	0.0184
Slope	-2.34283	1.61737	-1.44854	0.1855

Source: own construction

In the case that the estimates of the 3rd and 4th quarter of 2012 were actually marked in the square, and in the case, that the model would be recalculated, the slope probably would become statistically significant. Meanwhile is a correlation between inflation and unemployment rate only -0.46, i.e. a quite poor indirect dependency. Regression is shown in Figure 8.

Fig. 8 - Regression model for the situation in Czech Republic from 1st quarter 2010 to 2nd quarter 2012, where INFLAT is Consumer Price Index (+100 %, the average of 2005 is 100 %) and UNEMP is unemployment rate in %.

Source: own construction.

2. Vision and discussion about probable inflation and unemployment rate arising from the Phillips curve

At the time of writing this study there have not been published yet any preliminary estimates of the inflation rate and the unemployment rate for 3rd and 4th quarter of 2012. Looking at the recorded values in Figure 7, let us imagine that the index of consumer prices for 3rd quarter could be 121.8 % and for the 4th quarter could be 122.4 %. Then the unemployment rate could be for example, 6.4 % in the 3rd or 6.05 % in the 4th quarter of 2012. If this situation happened, the result would look like the situation in Figure 9.

Fig. 9 - The situation of the Czech Republic from 1st quarter 2010 to 4th quarter 2012, where 3rd and 4th quarter 2012 is expectation, INFLAT is Consumer Price Index (+100 %, the average of 2005 is 100 %) and UNEMP is unemployment rate in %.

Source: CZSO, own construction.

If we use these additional estimated values in linear regression model, we obtain estimates of the regression line, which will be already statistically significant. There is neither autocorrelation, nor heteroscedasticity at the 5% significance level in the model.

Table 4 - Linear regression model, situation from 1st quarter 2010 to 4th quarter 2012 (3rd and 4th quarter 2012 is expectation) and change to statistical significance of slope.

Parameter	Estimate	St. Error	T Statistic	P-Value
Intercept	43.7669	9.15849	4.77884	0.0007
Slope	-3.78303	1.33343	-2.83707	0.0176

Source: own construction

The correlation between inflation and unemployment rate is -0.67, i.e. a medium strong indirect dependency. Adjusted index of determination $adj.R^2$ is 40 %. The final regression is shown in Figure 10.

Fig. 10 - Regression model for the situation in Czech Republic from 1st quarter 2010 to 4th quarter 2012, where INFLAT is Consumer Price Index (+100 %, the average of 2005 is 100 %) and UNEMP is unemployment rate in %.

Source: own construction.

3. Stochastic modelling of inflation and unemployment rate

In order to estimate future development of inflation and unemployment rate by sophisticated method, Box and Jenkins approach for stochastic modelling of time series was used. For a time series consumer price indices there was identified ARIMA model (1, 0, 0) and final estimate is shown in Table 5.

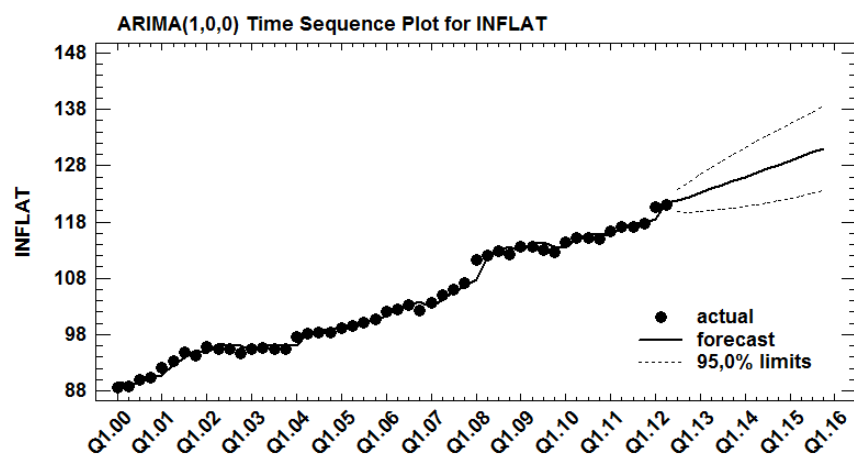

Table 5 - ARIMA (1, 0, 0) model for Consumer Price Index (inflation rate).

Parameter	Estimate	St. Error	T Statistic	P-Value
AR(1)	1.00566	0.0012469	806.501	0.0000

Source: own construction

The diagnostic tests indicate absence of autocorrelation and heteroscedasticity at the 5% significance level. From the model above there were constructed the predictions of indices of consumer prices up to 4th quarter of 2015. This development with 95 % confidence intervals is shown in Figure 11 and in Table 6.

Fig. 11 - The forecast of the development of Consumer Price Index (inflation rate) in the Czech Republic from 3rd quarter 2012 to 4th quarter 2015 (+100 %, the average of 2005 is 100 %).

Source: own construction.

Subsequently, there was identified ARIMA model (2, 1, 1) for the time series of unemployment rate and final estimate is shown in Table 7. The diagnostic tests again indicate the absence of autocorrelation and heteroscedasticity at the 5% significance level, and the forecast of unemployment rate up to 4th quarter of 2015 could be constructed. This forecast is shown in Figure 12 with calculated confidence intervals. For the purposes of possible further analyses there is the prediction of unemployment rate listed in Table 8. It is important to note that both forecast of the consumer price indices and forecast of the unemployment rates are based on the assumption of *ceteris paribus*.

Conclusion

Estimates of the consumer price indices and unemployment rate from the previous chapter were recorded in the chart of Phillips curve, which is shown in Figure 13. It is clear that the estimates reflect the zone of potential unemployment rate and rather prefer an acceleration of inflation over time. Partly, this is also confirmed by assumption of long-term Phillips curve, which takes the form of vertical.

Fig. 13 - The development of Phillips curve for the Czech Republic from 1st quarter 2000 to 4th quarter 2015, (3rd quarter 2012 – 4th quarter 2015 is forecast – future long term equilibrium), where INFLAT is Consumer Price Index (+100 %, the average of 2005 is 100 %) and UNEMP is unemployment rate in %.

Source: CZSO, own construction.

The forecasts in this study are based on the assumption of *ceteris paribus*. Unexpected interference in the economy may threaten their stability. It is important to note that the study showed that the Phillips curve for the Czech Republic can be used as a tool to show the relationship between inflation and unemployment rate at least for a period of several economic cycles. There are countries where assumptions of Phillips curve has never worked or worked poorly.
